Technology

Receipto currently uses a multitude of technologies ranging from artificial intelligence, to NFC (Near Field Communication). Here is what Receipto uses.

Artificial intelligence

I use AI to assign categories to the individual items. This allows Receipto to give a more granular analytical overview than other apps offer. I also use this to assign CO_2 values to items as it can cover all items.

NFC

NFC is used to transfer the receipt record ID (A link to the record in the database), from the payment system to the users phone. This record then gets linked to the users account.

React-Native - UI Framework

I have used React-Native to create the look and feel of the app. This is a widely used and modern framework that gives me the freedom to create what I design. I also use this to talk to my back-end API server to pull receipts and analytics from my receipt database.

Internet of things

I also plan to integrate Samsung smart devices, like Samsung's Smart washing machine, into the app so you can track how much CO_2 you are using with these devices. This would give you bonus points as well.

Social network

I will implement a social network into the Receipto app to allow users to have friends, view each others statistics and worlds, complete community goals, join leader boards, earn bonus points and more to come.

Rest API Backend

I have created a Rest API back-end for retrieving receipt records for the app and generating analytics. This simplifies the retrieval process and allows me more flexibility.
