Current state of the app

Currently I have multiple features already in a working state.

Artificial intelligence
The AI currently assigns each item a category automatically when the receipt gets added to the database.

NFC
The NFC works. So I currently have an NFC tag with a receipt record ID. The phone scans the tag and receives the code. The app then pulls the receipt from the database and links it to the users account.

React-Native - UI Framework
I have created the app using React-Native. This has allowed me to customise the app to my liking and to implement features like NFC, receipt retrieval via a back-end API, analytics generation and presentation, and a secure login and register system using Google's Firebase.

Social network
I currently have a very basic system where you can see other users on a leader board for the following statistics: Most spent, Most receipts collected, Most Items collected.

Rest API Backend
I have a Rest API back-end where I can send HTTP requests, and receive back the desired receipt, user data, item data, categories analytics, and I can add more if necessary.
